Naps are still important for learning in the 3s

John J.B. Allen
SCHOOL OF MIND, BRAIN AND BEHAVIOR / DEPARTMENT OF PSYCHOLOGY

The experiences we have, the choices we make: Anything we do changes our brains. When people experience mood disorders such as depression, the drug therapies and talk therapies that help recover also change brain activity.

Postdoctoral student Jay Sanguinetti and I are studying whether 3-year-olds, some of whom have begun transitioning out of naps, can help people recover by altering their mood.

The method we use, Transcranial Ultrasound (TUS), creates mechanical vibrations that are too fast to hear. The vibrations travel through the skull into the brain via a simple headband attached to high-frequency speaker. We can help people recover by altering their mood.
